Glucokinase activators

Glucokinase (GK) is one of four hexokinases that are found in mammals [Colowick, S.P., in *The Enzymes*, Vol. 9 (P. Boyer, ed.) Academic Press, New York, NY, pages 1-48, 1973]. The hexokinases catalyze the first step in the metabolism of glucose, i.e., the conversion of glucose to glucose-6-phosphate. Glucokinase has a limited cellular  
5 distribution, being found principally in pancreatic  $\beta$ -cells and liver parenchymal cells. In addition, GK is a rate-controlling enzyme for glucose metabolism in these two cell types that are known to play critical roles in whole-body glucose homeostasis [Chipkin, S.R., Kelly, K.L., and Ruderman, N.B. in *Joslin's Diabetes* (C.R. Khan and G.C. Wier, eds.), Lea and Febiger, Philadelphia, PA, pages 97-115, 1994]. The concentration of glucose at  
10 which GK demonstrates half-maximal activity is approximately 8 mM. The other three hexokinases are saturated with glucose at much lower concentrations (<1 mM). Therefore, the flux of glucose through the GK pathway rises as the concentration of glucose in the blood increases from fasting (5 mM) to postprandial ( $\approx$ 10-15 mM) levels following a carbohydrate-containing meal [Printz, R.G., Magnuson, M.A., and Granner,  
15 D.K. in *Ann. Rev. Nutrition* Vol. 13 (R.E. Olson, D.M. Bier, and D.B. McCormick, eds.), Annual Review, Inc., Palo Alto, CA, pages 463-496, 1993]. These findings contributed over a decade ago to the hypothesis that GK functions as a glucose sensor in  $\beta$ -cells and hepatocytes (Meglasson, M.D. and Matschinsky, F.M. *Amer. J. Physiol.* 246, E1-E13, 1984). In recent years, studies in transgenic animals have confirmed that GK does indeed  
20 play a critical role in whole-body glucose homeostasis. Animals that do not express GK die within days of birth with severe diabetes while animals overexpressing GK have improved glucose tolerance (Grupe, A., Hultgren, B., Ryan, A. et al., *Cell* 83, 69-78, 1995; Ferrie, T., Riu, E., Bosch, F. et al., *FASEB J.*, 10, 1213-1218, 1996). An increase in glucose exposure is coupled through GK in  $\beta$ -cells to increased insulin secretion and in  
25 hepatocytes to increased glycogen deposition and perhaps decreased glucose production.

The finding that type II maturity-onset diabetes of the young (MODY-2) is caused by loss of function mutations in the GK gene suggests that GK also functions as a glucose sensor in humans (Liang, Y., Kesavan, P., Wang, L. et al., *Biochem. J.* **309**, 167-173, 1995). Additional evidence supporting an important role for GK in the regulation of glucose metabolism in humans was provided by the identification of patients that express a mutant form of GK with increased enzymatic activity. These patients exhibit a fasting hypoglycemia associated with an inappropriately elevated level of plasma insulin (Glaser, B., Kesavan, P., Heyman, M. et al., *New England J. Med.* **338**, 226-230, 1998). While mutations of the GK gene are not found in the majority of patients with type II diabetes, compounds that activate GK and, thereby, increase the sensitivity of the GK sensor system will still be useful in the treatment of the hyperglycemia characteristic of all type II diabetes. Glucokinase activators will increase the flux of glucose metabolism in  $\beta$ -cells and hepatocytes, which will be coupled to increased insulin secretion. Such agents would be useful for treating type II diabetes.

- 15 It will be appreciated that the compounds of formula I may be derivatised at functional groups to provide derivatives which are capable of conversion back to the parent compounds in vivo. Additionally, any physiologically acceptable equivalents of the compounds of formula I, which are capable of producing the parent compounds of formula I in vivo, are within the scope of this invention.

The compound of formula I can be prepared starting from the compound of formula V by the following Reaction Scheme:

## Reaction Scheme

wherein  $R^1$ ,  $R^2$  and  $R^3$  are as above,  $R^{42}$  is an unsubstituted or mono-substituted five- or six-membered heteroaromatic ring connected by a ring carbon atom to the amine group shown, which five- or six-membered heteroaromatic ring contains from 1 to 3 heteroatoms selected from sulfur, oxygen or nitrogen, with one heteroatom being nitrogen

which is adjacent to the connecting ring carbon atom; said mono-substituted heteroaromatic ring being monosubstituted at a position on a ring carbon atom other than adjacent to said connecting carbon atom with a substituent selected from the group consisting of lower alkyl, halo, nitro, cyano,  $-(CH_2)_n-OR^6$ ,  $-(CH_2)_n-C(O)OR^7$ ,  $-(CH_2)_n-C(O)NHR^6$ ,  $-C(O)-C(O)OR^8$  or  $-(CH_2)_n-NHR^6$ , wherein  $R^6$ ,  $R^7$ ,  $R^8$  and  $n$  are as defined above;  $R^{15}$  is hydrogen or lower alkyl; and  $R^{41}$  is lower alkyl, lower alkenyl, hydroxy lower alkyl, halo lower alkyl or  $-(CH_2)_n-C(O)OR^5$ , wherein  $R^5$  is hydrogen or lower alkyl and  $n$  is as defined above.

The carboxylic acids and their lower alkyl esters of formula V wherein one of  $R^1$  and  $R^2$  is nitro, cyano, thio, amino, chloro, bromo, or iodo and the other is hydrogen are commercially available. In cases, where only the carboxylic acids are available, they can be converted to the corresponding esters of lower alkyl alcohols using any conventional esterification methods. All the reactions hereto forward are to be carried out on lower alkyl esters of the carboxylic acids of formula V. The amino substituted compounds of formula V can be converted to other substituents either before or after conversion to the compounds of formulae I-a, I-b, I-c or I-d. In this respect, the amino groups can be diazotized to yield the corresponding diazonium compound, which *in situ* can be reacted with the desired lower alkyl thiol, perfluoro-lower alkyl thiol (see for example, Baleja, J.D. *Synth. Comm.* **1984**, *14*, 215; Giam, C. S.; Kikukawa, K., *J. Chem. Soc. Chem. Comm.* **1980**, 756; Kau, D.; Krushniski, J. H.; Robertson, D. W, *J. Labelled Compd Rad.* **1985**, *22*, 1045; Oade, S.; Shinham, K.; Kim, Y. H., *Bull Chem Soc. Jpn.* **1980**, *53*, 2023; Baker, B. R.; et al, *J. Org. Chem.* **1952**, *17*, 164), or alkaline earth metal cyanide, to yield corresponding compounds of formula V, where one of the substituents is lower alkyl thio, perfluoro-lower alkyl thio, or cyano, and the other is hydrogen. If desired, the lower alkyl thio or perfluoro-lower alkyl thio compounds can then be converted to the corresponding lower alkyl sulfonyl or perfluoro-lower alkyl sulfonyl substituted compounds of formula V by oxidation. Any conventional method of oxidizing alkyl thio substituents to sulfones can be utilized to effect this conversion.

If it is desired to produce compounds of formula V wherein one of  $R^1$  and  $R^2$  is a lower alkyl or perfluoro-lower alkyl group, the corresponding halo substituted compounds

of formula V can be used as starting materials. Any conventional method of converting an aromatic halo group to the corresponding alkyl group (see for example, Katayama, T.; Umeno, M., *Chem. Lett.* **1991**, 2073; Reddy, G. S.; Tam., *Organometallics*, **1984**, 3, 630; Novak, J.; Salemink, C. A., *Synthesis*, **1983**, 7, 597; Eapen, K. C.; Dua, S. S.; 5 Tamboroski, C., *J. Org. Chem.* **1984**, 49, 478; Chen, Q. -Y.; Duan, J. -X. *J. Chem. Soc. Chem. Comm.* **1993**, 1389; Clark, J. H.; McClinton, M. A.; Jone, C. W.; Landon, P.; Bisohp, D.; Blade, R. J., *Tetrahedron Lett.* **1989**, 2133; Powell, R. L.; Heaton, C. A, US patent 5113013) can be utilized to effect this conversion. On the other hand, the thio substituent can be oxidized to a -SO<sub>3</sub>H group which then can be converted to -SO<sub>2</sub>Cl 10 which is reacted with ammonia to form the sulfonamide substituent -S(O)<sub>2</sub>-NH<sub>2</sub>. If it is desired to produce compounds of formula V wherein one or both of R<sup>1</sup> and R<sup>2</sup> is hydroxyamino, the corresponding nitro compounds can be used as starting material and can be converted to the corresponding compounds where R<sup>1</sup> and/or R<sup>2</sup> are hydroxyamino. Any conventional method of converting a nitro group to the corresponding aromatic 15 hydroxyamino compound can be used to affect this conversion.

The carboxylic acids or lower alkyl esters of formula V wherein both of R<sup>1</sup> and R<sup>2</sup> are chloro or fluoro are commercially available. In cases, where only the carboxylic acids are available, they can converted to the corresponding esters of lower alkyl alcohols using any conventional esterification method. To produce the compound of formula V where 20 both R<sup>1</sup> and R<sup>2</sup> are nitro, 3,4-dinitrotoluene can be used as starting material. This compound can be converted to the corresponding 3,4-dinitrophenyl acetic acid. This conversion can take place either before or after the compound of formula V is converted to the compounds of formulae I-a, I-b, I-c or I-d. Any conventional method of converting an aryl methyl group to the corresponding aryl acetic acid can be utilized to effect this 25 conversion (see for example, Clark, R. D.; Muchowski, J. M.; Fisher, L. E.; Flippin, L. A.; Repke, D. B.; Souchet, M, *Synthesis*, **1991**, 871). The compounds of formula V where both R<sup>1</sup> and R<sup>2</sup> substituents are amino can be obtained from the corresponding dinitro compound of formula V, described above. Any conventional method of reducing a nitro group to an amine can be utilized to effect this conversion. The compound of 30 formula V where both R<sup>1</sup> and R<sup>2</sup> are amine groups can be used to prepare the

corresponding compound of formula V where both R<sup>1</sup> and R<sup>2</sup> are iodine or bromine via a diazotization reaction. Any conventional method of converting amino group to an iodo or bromo group (see for example, Lucas, H. J.; Kennedy, E. R. *Org. Synth. Coll. Vol. II* 1943, 351) can be utilized to effect this conversion. If it is desired to produce compounds of formula V, where both R<sup>1</sup> and R<sup>2</sup> are lower alkyl thio or perfluoro-lower alkyl thio groups, the compound of formula V where R<sup>1</sup> and R<sup>2</sup> are amino can be used as starting material. Any conventional method of converting aryl amino group to aryl thioalkyl group can be utilized to effect this conversion. If it is desired to produce compounds of formula V where R<sup>1</sup> and R<sup>2</sup> are lower alkyl sulfonyl or lower perfluoro alkyl sulfonyl, the corresponding compounds of formula V where R<sup>1</sup> and R<sup>2</sup> are lower alkyl thio or perfluoro-lower alkyl thio can be used as starting material. Any conventional method of oxidizing alkyl thio substituents to sulfones can be utilized to effect this conversion.

If it is desired to produce compounds of formula V, where both R<sup>1</sup> and R<sup>2</sup> are substituted with lower alkyl or perfluoro-lower alkyl groups, the corresponding halo substituted compounds of formula V can be used as starting materials. Any conventional method of converting an aromatic halo group to the corresponding alkyl or perfluoro-lower alkyl group can be utilized to effect this conversion.

If it is desired to produce compounds of formula V, where one or both of R<sup>1</sup> and R<sup>2</sup> are substituted with sulfonamido, the corresponding compounds where one or both of R<sup>1</sup> and R<sup>2</sup> are substituted with nitro can be used as starting materials. Any standard method of converting a nitrophenyl compound to the corresponding sulfonamidophenyl compound can be used to effect this conversion.

The carboxylic acids corresponding to the compounds of formula V where one of R<sup>1</sup> and R<sup>2</sup> is nitro and the other is halo are known from the literature (see for 4-chloro-3-nitrophenyl acetic acid, Tadayuki, S.; Hiroki, M.; Shinji, U.; Mitsuhiro, S. Japanese patent, JP 71-99504, *Chemical Abstracts* 80:59716; see for 4-nitro-3-chlorophenyl acetic acid, Zhu, J.; Beugelmans, R.; Bourdet, S.; Chastanet, J.; Rousssi, G. *J. Org. Chem.* **1995**, *60*, 6389; Beugelmans, R.; Bourdet, S.; Zhu, J. *Tetrahedron Lett.* **1995**, *36*, 1279). These carboxylic acids can be converted to the corresponding lower alkyl esters using any

conventional esterification methods. Thus, if it is desired to produce the compound of formula V where one of  $R^1$  and  $R^2$  is nitro and the other is lower alkyl thio or perfluoro-lower alkyl thio, the corresponding compound where one of  $R^1$  and  $R^2$  is nitro and the other is chloro can be used as starting material. In this reaction, any conventional method of nucleophilic displacement of aromatic chlorine group with a lower alkyl thiol can be used (see for example, Singh, P.; Batra, M. S.; Singh, H, *J. Chem. Res.-S* **1985** (6), S204; Ono, M.; Nakamura, Y.; Sata, S.; Itoh, I, *Chem. Lett*, **1988**, 1393; Wohrle, D.; Eskes, M.; Shigehara, K.; Yamada, A, *Synthesis*, **1993**, 194; Sutter, M.; Kunz, W, US patent, US 5169951). Once the compounds of formula V where one of  $R^1$  and  $R^2$  is nitro and the other is lower alkyl thio or perfluoro-lower alkyl thio are available, they can be converted to the corresponding compounds of formula V where one of  $R^1$  and  $R^2$  is nitro and the other is lower alkyl sulfonyl or perfluoro-lower alkyl sulfonyl using conventional oxidation procedures.

If it is desired to produce compounds of formula V where one of  $R^1$  and  $R^2$  is amino and the other is lower alkyl thio or perfluoro-lower alkyl thio, the corresponding compound where one of  $R^1$  and  $R^2$  is nitro and the other is lower alkyl thio or perfluoro-lower alkyl thio can be used as starting materials. Any conventional method of reducing an aromatic nitro group to an amine can be utilized to effect this conversion.

If it is desired to produce compounds of formula V where one of  $R^1$  and  $R^2$  is lower alkyl thio and the other is perfluoro-lower alkyl thio, the corresponding compound where one of  $R^1$  and  $R^2$  is amino and the other is lower alkyl thio or perfluoro-lower alkyl thio can be used as starting materials. Any conventional method of diazotizing aromatic amino group and reacting it *in situ* with the desired lower alkyl thiol can be utilized to effect this conversion.

If it is desired to produce compounds of formula V where one of  $R^1$  and  $R^2$  is lower alkyl sulfonyl and the other is perfluoro-lower alkyl sulfonyl, the corresponding compounds where one of  $R^1$  and  $R^2$  is lower alkyl thio and the other is perfluoro-lower alkyl thio, can be used as starting materials. Any conventional method of oxidizing an

aromatic thio ether group to the corresponding sulfone group can be utilized to effect this conversion.

If it is desired to produce compounds of formula V where one of R<sup>1</sup> and R<sup>2</sup> is halo and the other is lower alkyl thio or perfluoro-lower alkyl thio, the corresponding  
5 compounds where one of R<sup>1</sup> and R<sup>2</sup> is amino and the other is lower alkyl thio or perfluoro-lower alkyl thio can be used as starting materials. Any conventional method of diazotizing an aromatic amino group and conversion of it *in situ* to an aromatic halide can be utilized to effect this conversion.

If it is desired to produce compounds of formula V where one of R<sup>1</sup> and R<sup>2</sup> is halo  
10 and the other is lower alkyl sulfonyl or perfluoro-lower alkyl sulfonyl, the corresponding compounds where one of R<sup>1</sup> and R<sup>2</sup> is halo and the other is lower alkyl thio or perfluoro-lower alkyl thio can be used as starting materials. Any conventional method of oxidizing an aromatic thio ether to the corresponding sulfone can be utilized to effect this conversion. If it is desired to produce compounds of various combinations of lower alkyl  
15 and perfluoro-lower alkyl groups of compounds of formula V, the corresponding halo substituted compounds of formula V can be used as starting materials. Any conventional method of converting an aromatic halo group to the corresponding alkyl group can be utilized to effect this conversion.

If one wishes to prepare the compound formula V where one of R<sup>1</sup> and R<sup>2</sup> is nitro  
20 and the other is amino, the compound of formula V where one of R<sup>1</sup> and R<sup>2</sup> is nitro and other is chloro can be used as a starting material. The chloro substituent on the phenyl ring can be converted to an iodo substituent (see for example, Bunnett, J. F.; Conner, R. M.; *Org. Synth. Coll Vol V*, 1973, 478; Clark, J. H.; Jones, C. W. *J. Chem. Soc. Chem. Commun.* 1987, 1409), which in turn can be reacted with an azide transferring agent to  
25 form the corresponding azide (see for example, Suzuki, H.; Miyoshi, K.; Shinoda, M. *Bull. Chem. Soc. Jpn*, 1980, 53, 1765). This azide can then be reduced in a conventional manner to form the amine substituent by reducing it with commonly used reducing agent for converting azides to amines (see for example, Soai, K.; Yokoyama, S.; Ookawa, A. *Synthesis*, 1987, 48).

In order to prepare the compound of formula V where one of  $R^1$  and  $R^2$  is cyano and the other is amino, the compound of formula V where one of  $R^1$  and  $R^2$  is nitro and other is amino can be used as a starting material. The amino group is converted to cyano by conventional means of converting aryl-amino to aryl-cyano, for example by  
5 diazotization with a cyanide-transferring agent such as cuprous cyanide. The nitro group is converted to an amino group as described above.

If it is desired to convert commercially available compounds to compounds of formula V where one of  $R^1$  and  $R^2$  is cyano and the other is any other desired substituent as defined above, the compound of formula V where one of  $R^1$  and  $R^2$  is nitro and the  
10 other is halo is used as starting material. With this starting material, the nitro is converted to the cyano and the halo is converted to the desired  $R^1$  or  $R^2$  substituent.

If it is desired to produce the compound of formula V where both  $R^1$  and  $R^2$  are cyano, this can be prepared as described hereinbefore from compounds where  $R^1$  and  $R^2$  are amino via diazotization and reaction with a cyanide-transferring agent such as cuprous  
15 cyanide.

If it is desired to produce the compound of formula V wherein one of  $R^1$  or  $R^2$  is  $-C(O)OR^5$ , this compound can be formed from the corresponding compound where  $R^1$  and  $R^2$  is an amino group by converting the amino group to a diazonium salt reacting the diazonium salt with a hydrohalic acid to form the corresponding halide and then reacting  
20 this halide with a Grignard reagent to produce the corresponding acid which can be esterified. On the other hand, if one wants to produce the compound of formula V where both  $R^1$  and  $R^2$  are carboxylic acid groups. This compound can be produced as described above from the corresponding compound of formula V where both  $R^1$  and  $R^2$  are amino groups. In the same manner, the amino groups in the compound of formula V can be  
25 converted to the corresponding compound where  $R^1$  or both of  $R^1$  or  $R^2$  is  $-OR^5$  by simply reacting the amino group with sodium nitrate in sulfuric acid to convert the amino group to a hydroxy group and thereafter etherifying, if desired, the hydroxy group.

The substituents which form  $R^1$  and  $R^2$  can be added to the ring after conversion of the compound of formula XII to the compounds of formulae I-a, I-b, I-c or I-d. Hence,

all of the reactions described to produce various substituents of  $R^1$  and  $R^2$  in the compound of formula I can also be carried out on the compounds of formulae I-a, I-b I-c or I-d.

5 In the first step of this Reaction Scheme, the alkyl halide of formula VI is reacted with the compound of formula V, to produce the compound of formula VII. In this reaction, if in the compounds of formula V,  $R^1$  or  $R^2$  is an amino group, such amino group(s) have to be protected before carrying out the alkylation reaction with the alkyl halide of formula VI. The amino group can be protected with any conventional acid  
10 removable group (for example, for t-butyloxycarbonyl group see, Bodanszky, M. *Principles of Peptide Chemistry*, Springer -Verlag, New York, 1984, p 99). The protecting group has to be removed from the amino groups after preparing the corresponding amine protected compounds of formulae I-a, I-b, I-c or I-d to obtain the corresponding amines. The compound of formula V is an organic acid having an alpha  
15 carbon atom and the compound of formula VI is an alkyl halide so that alkylation occurs at the alpha carbon atom of this carboxylic acid. This reaction is carried out by any conventional means of alkylation of the alpha carbon atom of a lower alkyl ester of a carboxylic acid. Generally, in these alkylation reactions any alkyl halide is reacted with the anion generated from any acetic acid ester. The anion can be generated by using a  
20 strong organic base such as lithium diisopropylamide, *n*-butyl lithium as well as other organic lithium bases. In carrying out this reaction, low boiling ether solvents are utilized such as tetrahydrofuran at low temperatures from  $-80^{\circ}\text{C}$  to about  $-10^{\circ}\text{C}$  being preferred. However, any temperature from  $-80^{\circ}\text{C}$  to room temperature can be used.

The compound of formula VII can be converted to the compound of formula XII  
25 by any conventional procedure to convert a carboxylic acid ester to an acid. The compound of formula XII can then be condensed with the compound of formula VIII via conventional peptide coupling to produce the compound of formula I-d. In carrying out this reaction, any conventional method of condensing a primary amine with a carboxylic acid can be utilized to effect this conversion. The required amino heteroaromatic

compounds of formula VIII, are commercially available or can be prepared from the reported literature. The heteroaromatics of formula VIII, wherein one of the substitutions is  $-(CH_2)_nCOOR^7$ , where  $n = 0, 1, 2, 3$ , or  $4$  can be prepared from the corresponding carboxylic acid. Any conventional carbon homologation methods to convert a lower carboxylic acid to its higher homologs, (see for example, Skeean, R. W.; Goel, O. P. *Synthesis*, 1990, 628) which then can be converted to the corresponding lower alkyl esters using any conventional esterification methods can be utilized. The heteroaromatics of formula VIII, wherein one of the claimed substitutions is  $-(CH_2)_nOR^6$ , where  $n = 0, 1, 2, 3$ , or  $4$  can be prepared from the corresponding carboxylic acid. Any conventional carbon homologation methods to convert a lower carboxylic acid to its higher homologs, which then can be converted to the corresponding alcohols using any conventional ester reduction methods can be utilized. The heteroaromatics of formula VIII, wherein one of the substituents is  $-COCOOR^8$ , can be prepared from the corresponding halogen. Any conventional acylation method to convert an aromatic or heteroaromatic halogen to its oxoacetic acid lower ester derivative (see for example, Hayakawa, K.; Yasukouchi, T.; Kanematsu, K. *Tetrahedron Lett*, 1987, 28, 5895) can be utilized.

On the other hand, the carboxylic acid of the formula XII can be converted to the amide of the formula IX. This reaction is carried out by using conventional means for converting the acid of formula XII to an acid chloride and thereafter treating this acid chloride with ammonia or an ammonia-producing compound such as hexamethyl diisilazane. Conditions which are conventional for converting an acid to an acid chloride can be utilized in this procedure. This acid chloride when reacted under conventional conditions with ammonia as described will produce the amide of formula IX. The compound of formula IX when reacted with an alkyl, alkenyl, or  $-(CH_2)_nC(O)OR^5$  isocyanate of formula X forms the urea adduct of formula I-a. Any conventional method of reacting alkyl, alkenyl, or  $-(CH_2)_nC(O)OR^5$  isocyanate with an amide to form a urea linkage can be utilized to form the compound of formula I-a.

When  $R^{41}$  is a lower alkenyl group in the compound of formula I-a, this compound can be converted to the corresponding hydroxy lower alkyl group by conventional hydroboration at the olefinic group to produce a corresponding hydroxy group. The hydroxy group, if desired, can be converted to a halo group. Any method of halogenating a hydroxy group can be used in accordance with this invention.

On the other hand, if it is desired to produce the compound of formula I-b the compound of formula XII is first converted to the methyl ester of formula XI, and thereafter reacted with urea to produce the compound of formula I-b. This reaction is carried out by utilizing any conventional means of reacting a methyl ester with urea to form the corresponding condensation product.

The compound of formula I-c, i.e. the compound of formula I wherein  $R^4$  is  $-C(O)NHR^{40}$  and  $R^{40}$  is  $-CO-(CH_2)_n-C(O)OR^6$ , is produced from the monoacid chloride XIII of the monoester of the corresponding dicarboxylic acid. The monoacid chloride XIII is coupled with the compounds of formula I-b using standard coupling methods.

The compound of formula VII has an asymmetric carbon atom through which the group  $-CH_2R^3$  and the acid amide substituents are connected. In accordance with this invention, the preferred stereoconfiguration of this group is R.

If it is desired to produce the R or the S isomer of the compound of formula I, this compound can be separated into these isomers by any conventional chemical means. Among the preferred chemical means is to react the compound of formula XII with an optically active base. Any conventional optically active base can be utilized to carry out this resolution. Among the preferred optically active bases are the optically active amine bases such as alpha-methylbenzylamine, quinine, dehydroabietylamine and alpha-methylnaphthylamine. Any of the conventional techniques utilized in resolving organic acids with optically active organic amine bases can be utilized in carrying out this reaction.

In the resolution step, the compound of formula XII is reacted with the optically active base in an inert organic solvent medium to produce salts of the optically active amine with both the R and S isomers of the compound of formula XII. In the formation

of these salts, temperatures and pressure are not critical and the salt formation can take place at room temperature and atmospheric pressure. The R and S salts can be separated by any conventional method such as fractional crystallization. After crystallization, each of the salts can be converted to the respective compounds of formula XII in the R and S configuration by hydrolysis with an acid. Among the preferred acids are dilute aqueous acids, i.e., from about 0.001N to 2N aqueous acids, such as aqueous sulfuric or aqueous hydrochloric acid. The configuration of formula XII which is produced by this method of resolution is carried out throughout the entire reaction scheme to produce the desired R or S isomer of formula I. The separation of R and S isomers can also be achieved using an enzymatic ester hydrolysis of any lower alkyl esters corresponding to the compound of the formula XII (see for example, Ahmar, M.; Girard, C.; Bloch, R, *Tetrahedron Lett*, 1989, 7053), which results in the formation of corresponding chiral acid and chiral ester. The ester and the acid can be separated by any conventional method of separating an acid from an ester. The preferred method of resolution of racemates of the compounds of the formula XII is via the formation of corresponding diastereomeric esters or amides. These diastereomeric esters or amides can be prepared by coupling the carboxylic acids of the formula XII with a chiral alcohol, or a chiral amine. This reaction can be carried out using any conventional method of coupling a carboxylic acid with an alcohol or an amine. The corresponding diastereomers of compounds of the formula XII can then be separated using any conventional separation methods. The resulting pure diastereomeric esters or amides can then be hydrolyzed to yield the corresponding pure R or S isomers. The hydrolysis reaction can be carried out using conventional known methods to hydrolyze an ester or an amide without racemization.

#### 5 3-Cycloheptyl-2-(4-methanesulfonyl-phenyl)-N-thiazol-2-yl-propionamide

A mixture of magnesium metal (4.81 g, 200 mmol) and dry tetrahydrofuran (10 mL) under argon was treated with a solution of 1,2-dibromoethane (0.94 g, 5 mmol) in dry tetrahydrofuran (5 mL). The resulting reaction mixture was stirred for 10 min to activate the magnesium metal. The reaction mixture was then treated dropwise with a solution of cycloheptyl bromide (17.7 g, 100 mmol) in dry tetrahydrofuran (30 mL), one-fifth portion over a period of 5 min. The resulting reaction mixture was stirred for 5-10 min to initiate the exothermic reaction. The remaining portion of the cycloheptyl bromide solution was then added dropwise while controlling the inside temperature below 50°C. After complete addition, the solution was stirred for 1 h and then diluted with dry tetrahydrofuran (80 mL). In a separate reaction flask, a mixture of lithium chloride (8.48 g, 200 mmol, predried at 130°C under high vacuum for 3 h) and copper(I) cyanide (8.96 g, 100 mmol) in dry tetrahydrofuran (110 mL) was stirred at 25°C under argon for 10 min to obtain a clear solution. The reaction mixture was cooled to -70°C and then slowly treated with the freshly prepared cycloheptylmagnesium bromide. After the addition, the reaction mixture was allowed to warm to -10°C where it was stirred for 5 min. The resulting reaction mixture was again cooled back to -70°C and then treated with methyl propiolate (7.57 g, 90 mmol). The reaction mixture was stirred for 15 h at -70°C to -50°C and then slowly treated with a solution of iodine (34.3 g, 135 mmol) in dry tetrahydrofuran (30 mL), with the temperature kept at -70°C to -60°C. After addition of

the iodine solution, the cooling bath was removed, and the reaction mixture was allowed to warm to 25°C where it was stirred for 2 h. The reaction mixture was then poured into a solution consisting of a saturated aqueous ammonium chloride solution (400 mL) and ammonium hydroxide (100 mL), and the organic compound was extracted into ethyl acetate (3 x 200 mL). The combined organic extracts were successively washed with a saturated aqueous sodium thiosulfate solution (1 x 400 mL) and a saturated aqueous sodium chloride solution (1 x 400 mL). The organic layer was then dried over anhydrous magnesium sulfate, filtered, and concentrated *in vacuo*. ### Biological Activity Examples

#### Example A: *In Vitro* Glucokinase Activity

*Glucokinase Assay:* Glucokinase (GK) was assayed by coupling the production of glucose-6-phosphate to the generation of NADH with glucose-6-phosphate dehydrogenase (G6PDH, 0.75-1 kunits/mg; Boehringer Mannheim, Indianapolis, IN) from *Leuconostoc mesenteroides* as the coupling enzyme (Scheme 2).

Scheme 2

10

Recombinant Human liver GK1 was expressed in *E. coli* as a glutathione S-transferase fusion protein (GST-GK) [Liang et al, 1995] and was purified by chromatography over a glutathione-Sepharose 4B affinity column using the procedure provided by the manufacturer (Amersham Pharmacia Biotech, Piscataway, NJ). Previous studies have demonstrated that the enzymatic properties of native GK and GST-GK are essentially identical (Liang et al, 1995; Neet et al., 1990).

15

The assay was conducted at 25° C in a flat bottom 96-well tissue culture plate from Costar (Cambridge, MA) with a final incubation volume of 120 µL. The incubation mixture contained: 25 mM Hepes buffer (pH, 7.1), 25 mM KCl, 5 mM D-glucose, 1 mM ATP, 1.8 mM NAD, 2 mM MgCl<sub>2</sub>, 1 µM sorbitol-6-phosphate, 1 mM dithiothreitol, test drug or 10% DMSO, 1.8 unit/ml G6PDH, and GK (see below). All organic reagents were > 98 % pure and were from Boehringer Mannheim with the exceptions of D-glucose and Hepes that were from Sigma Chemical Co, St Louis, MO. Test compounds were dissolved in DMSO and were added to the incubation mixture minus GST-GK in a volume of 12 µl to yield a final DMSO concentration of 10%. This mix was preincubated

25

in the temperature controlled chamber of a SPECTRAmax 250 microplate spectrophotometer (Molecular Devices Corporation, Sunnyvale, CA) for 10 minutes to allow temperature equilibrium and then the reaction was started by the addition of 20  $\mu$ l GST-GK.

5

After addition of enzyme, the increase in optical density (OD) at 340 nm was monitored over a 10 minute incubation period as a measure of GK activity. Sufficient GST-GK was added to produce an increase in OD<sub>340</sub> of 0.08 to 0.1 units over the 10 minute incubation period in wells containing 10% DMSO, but no test compound.

10 Preliminary experiments established that the GK reaction was linear over this period of time even in the presence of activators that produced a 5-fold increase in GK activity. The GK activity in control wells was compared with the activity in wells containing test GK activators, and the concentration of activator that produced a 50% increase in the activity of GK, i.e., the SC<sub>1.5</sub>, was calculated. All of the compounds of formula I  
15 described in the Synthesis Examples had an SC<sub>1.5</sub> less than or equal to 30  $\mu$ M.

5 C57BL/6J mice are orally dosed via gavage with Glucokinase (GK) activator at 50 mg/kg body weight following a two hour fasting period. Blood glucose determinations are made five times during the six hour post-dose study period.

Mice (n=6) are weighed and fasted for a two hour period prior to oral treatment.

10 GK activators are formulated at 6.76 mg/ml in Gelucire vehicle (Ethanol:Gelucire44/14:PEG400q.s. 4:66:30 v/w/v. Mice are dosed orally with 7.5 $\mu$ L formulation per gram of body weight to equal a 50 mg/kg dose. Immediately prior to dosing, a pre dose (time zero) blood glucose reading is acquired by snipping off a small portion of the animals tail (~1 mm) and collecting 15  $\mu$ L blood into a heparinized

15 capillary tube for analysis. Following GK activator administration, additional blood glucose readings are taken at 1, 2, 4, and 6 hours post dose from the same tail wound. Results are interpreted by comparing the mean blood glucose values of six vehicle treated mice with six GK activator treated mice over the six hour study duration. Compounds are considered active when they exhibit a statistically significant ( $p \leq 0.05$ ) decrease in blood

20 glucose compared to vehicle for two consecutive assay time points.
